

CHAPTER IIITHERMODYNAMIC PROTON-LIGAND STABILITY CONSTANTS OF  
HYDROXAMIC ACIDSABSTRACT

The thermodynamic proton-ligand stability constants,  $pK_a$ , of the N-p-chlorophenyl-m-substituted benzohydroxamic acids have been determined in dioxan-water media [50-70% (v/v)] at  $25 \pm 0.1^\circ\text{C}$ . Empirical correction to pH meter readings in mixed aqueous media have been applied. The  $pK_a$  varies linearly with mole fraction of dioxan. Numerical equations expressing this linear relationship have been obtained using the method of least squares. The Hammett correlation function and the effect of substituents on ionization constants of hydroxamic acids is discussed.

THERMODYNAMIC PROTON-LIGAND STABILITY CONSTANTS OF  
HYDROXAMIC ACIDS

The physico-chemical properties of organic reagents are essential to understand their nature, reactivity and analytical applicability. Studies on the metal complexes and analytical applications of hydroxamic acids require a knowledge of their ionization constants. In recent years many analogous compounds have been prepared by introduction of various substituent groups in different positions in the hope of developing reagents with superior analytical properties.

In this portion of the investigation, proton-ligand stability constants (hereafter, termed as thermodynamic ionization constants,  $pK_a$ ) of N-p-chlorophenyl-m-substituted benzohydroxamic acids have been determined in 50-70% (v/v) dioxan-water media at  $25 \pm 0.1^\circ\text{C}$ .

All these hydroxamic acids are insoluble in water. Hence a resource to the use of mixed aqueous solvent media has to be taken to obtain the desired constants. Water dioxan solutions were deliberately chosen for this study for several reasons. The thermodynamic significance of results obtained with pH meter in these solutions is well understood as a result of thorough investigations by Van Uitert et al. (1,2), Agrawal et al. (3-5) and others (6-8).

# CALIBRATION OF GLASS ELECTRODE IN DIOXAN-WATER MEDIA

The use of mixed aqueous solvent necessitates the calibration of the glass electrode so that pH meter readings are valid for the system. Such calibration also affords a simple method for evaluation of thermodynamic data directly from the measurement.

Van Uitert and Haas (1,2) have established that the glass electrode can be calibrated to measure stoichiometric hydrogen ion concentration  $[H^+]$  from the pH metric reading (hereafter referred to as B when obtained from aqueous mixed solutions) in aqueous dioxan media by the relation

$$- \log [H^+] = B + \log U_H \quad (1)$$

$$\text{where } \log U_H = \log U_H^\circ + \log y_{\pm} \quad (2)$$

$$\text{or } - \log [H^+] = B + \log U_H^\circ + \log y_{\pm} \quad (3)$$

Here  $y_{\pm}$  denotes the mean activity coefficient of HCl for the solvent composition, temperature and ionic strength for which  $\log U_H$  has been determined and  $\log U_H^\circ$  corresponds to the correction at zero ionic strength which is dependent on the composition and temperature of the solvent medium. Equation (1) is equally valid for water and water-dioxan mixtures (1-5).

## CALCULATION OF THERMODYNAMIC IONIZATION CONSTANT

The thermodynamic dissociation constant  $K_a$  (aq) of hydroxamic acid, HA,

in an aqueous medium is given by equation (4) and (5),

$$K_a \text{ (aq)} = \frac{[\text{H}^+][\text{A}^-]}{[\text{HA}]} \frac{y_{\text{H}^+} y_{\text{A}^-}}{y_{\text{HA}}} \quad (4)$$

$$\text{p}K_a = -\log [\text{H}^+] + \log \frac{[\text{HA}]}{[\text{A}^-]} - 2 \log y_{\pm} \quad (5)$$

where  $y_{\pm}$  is the activity coefficient of a univalent ion ( $y_{\text{H}^+} = y_{\text{A}^-} = y_{\pm}$ ) at a given temperature and medium and it is assumed that the activity coefficient of the unionized acid  $y_{\text{HA}}$  is unity. The final expression for calculating ionization constant in dioxan-water medium is obtained by substituting the value of hydrogen ion concentration from equation (3) in equation (5).

$$\text{p}K_a = B + \log U_{\text{H}}^{\circ} + \log \frac{[\text{HA}]}{[\text{A}^-]} + \log \frac{1}{y_{\pm}} \quad (6)$$

The  $\text{p}K_a$  values thus obtained are termed as thermodynamic values as they include correction due to activity.

coefficients. The equation (6) can be written as

$$pK_a = B + \Delta$$

$$\text{where } \Delta = \log U_H^\circ + \log \frac{[HA]}{[A^-]} + \log \frac{1}{y_{\pm}} \quad (7)$$

## EXPERIMENTAL

### CHEMICALS

All the chemicals used were of G.R. (E. Merck) and AnalaR (B.D.H.) grades unless otherwise stated.

### SOLVENTS

Distilled water

Preparation of distilled water is described in Chapter II.

Dioxan

p-dioxan was purified by the procedure of Weissberger (9). It was refluxed over pellets of potassium hydroxide for about 8-10 hrs, distilled and middle fraction of the distillate refluxed over metallic sodium for 5-6 hrs, and fractionally distilled. The middle fraction was used. Its purity was established by freezing point, which varied from 11.65° to 11.80° (uncorrected) against the reported range of 11.65° to 12.0° (10,11).

### REAGENTS

Potassium hydroxide

Carbonate free potassium hydroxide was prepared according to the method described by Vogel (12) and diluted

to 0.1 M with the desired composition of dioxan-aqueous mixture.

#### Hydroxamic acid

The preparation of the hydroxamic acids is described in Chapter II. They were purified by recrystallisation from proper mixtures of benzene-petroleum ether before each investigation.

#### Standard Buffers

They were prepared as per reference from Vogel (12).

#### APPARATUS

A radiometer pH meter PHM 84 equipped with a combined electrode was used for pH metric titrations. The pH meter was standardised at the desired temperature ( $25 \pm 0.1^\circ\text{C}$ ) with aqueous buffer solutions such as 0.05 M potassium acid phthalate (pH - 4.005 at  $25^\circ\text{C}$ ) and 0.01 M borax (pH - 9.18 at  $25^\circ\text{C}$ ). Standardisation was checked both before and after each titration.

#### TITRATION VESSEL

A titration vessel, with a capacity of 75 ml was specially fabricated for the pH titrations. Besides an inlet from the side for nitrogen gas, it had three necks,

which accomodated the combined electrode and the microburette.

#### NITROGEN

Nitrogen gas was passed through a series of bubblers containing a saturated alkaline solution of pyrogallol, 2N sulphuric acid, distilled water and finally the required solvent.

#### PROCEDURE

Into a 75-ml three necked titration cell having an inlet for nitrogen, the weighed amount of hydroxamic acid (corresponding to 0.01 M in a final volume of 50 ml), freshly distilled dioxan (as required for the desired composition) and double distilled water (as required for the desired composition) were added to yield the final composition of dioxan-water media under study. Due allowance for the contraction in volume on mixing of two solvents was made. The titration cell was thermostated at  $25 \pm 0.1^\circ\text{C}$ . Nitrogen, presaturated with the volume percentage dioxan-water media under study was bubbled through the solution. The electrode was placed in the cell. This solution was titrated against 0.1 M KOH also prepared in the required volume percentage dioxan-water media under study, taken in a burette (least count - 0.02 ml) adding the same in small aliquots (0.5 ml) and the pH was recorded.

## RESULTS AND DISCUSSION

Hydroxamic acids are found to be the versatile analytical reagents (13-18). The acidity of the hydroxamic acids may be attributed essentially to the -OH group and basic character of nitrogen atom is suppressed as it is in amides. Hydroxamic acids are weak acids, though several times stronger than phenols. The suppression of acid character may be attributed to intramolecular hydrogen bonding as shown by infrared studies (19-21).

The acidic dissociation character of hydroxamic acids in ionizing solvents can be represented by the following equilibria.

and

Protonated  
species

Molecular  
species

Anion species

From the pH titrations performed here, it is inferred that the protonation of hydroxamic acids is relatively small.

The experimental observation for only three representative titrations are recorded in Tables 1-3. The values of  $pK_a$  of N-p-chlorophenyl-m-substituted benzohydroxamic acids in 50-70% (v/v) dioxan-water media at  $25 \pm 0.1^\circ\text{C}$  are given in Table 4. The average  $pK_a$  generally falls within a spread of  $\pm 0.02$  but not beyond  $\pm 0.03$  in any case. The empiricals for different mole fractions of dioxan are given in Table 5.

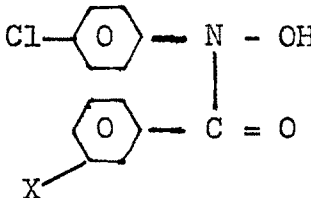

#### Medium Effect

In Figs. 1-2, the  $pK_a$  are plotted against mole fraction of dioxan,  $n_2$ , and a linear relationship is observed. The empirical values of  $pK_a$  indicate the maximum deviation from linearity of the order of about 0.5% in  $pK_a$ .

Generally, most of the hydroxamic acids have lower solubility in water consequently the equilibrium studies have been made in mixed solvent systems. Of the various solvent systems chosen the mixture of water and dioxan appears to be the most convenient. The reason may be due to the fact that a linear relationship exists between the ionization constants ( $pK_a$ ) of weak acids and mole fraction of dioxan (1-6, 22-25). In case of water-alcohol system, hockey-stick shape curves are obtained (26).

V N-p-chlorophenyl-m-chlorobenzohydroxamic acid.

The effect of solvent on the Gibbs energy for the dissociation of a weak acid has sometimes been ascribed to a change in the electrostatic self energy of the ions. Gurney (27) and others (28,29), have pointed out that the standard free energy change of proton transfer may be considered in two parts, electrostatic ( $\Delta G_{el}^\circ$ ) and non electrostatic ( $\Delta G_{non}^\circ$ ). The simplest expression for electrostatic energy of a mole of univalent ions is that of Born (30).

$$\Delta G_{el}^\circ = \frac{Ne^2}{2} \frac{1}{Dr_s} \quad (8)$$

where N is the Avogadro number, e is the electronic charge, D is the dielectric constant of the medium and  $r_s$  the radius of the (spherical) ion.

In the dissociation of a weak acid in the mixture of the solvents of a charge type  $HA \rightleftharpoons H^+ + A^-$ , the electrostatic forces between the cation and anions are increased and formation of molecular species is facilitated (24). The change in the energy on the transfer from water to 70 percent dioxan is then

$$\Delta G_{el}^\circ = \left( \frac{Ne^2}{2} \frac{1}{D_s} - \frac{1}{D_w} \right) \left( \frac{1}{r_+} - \frac{1}{r_-} \right) \quad (9)$$

where  $D_s$  is the dielectric constant of dioxan-water percent and  $D_w$  is that of water (78.36 at 25°C).

Further on substitution of  $\Delta G_{\text{diss}}^{\circ} = 2.303 RT pK_a$  becomes

$$pK_a = \frac{\Delta G_{\text{non}}^{\circ}}{2.303 RT} + \frac{Ne^2}{4.606 RT} \left( \frac{1}{D_s} - \frac{1}{D_w} \right) \left( \frac{1}{r_+} + \frac{1}{r_-} \right) \quad (10)$$

When the  $pK_a$  of hydroxamic acids are plotted against  $1/D$  (Fig. 3) it is observed that the plots possess the distinct curvature. This suggests non electrical forces which could include geometrical factors, hydrogen bonding and solvent solute interactions, influencing the dissociation process.

Agrawal et al. observed (4,5, 31-35) that the  $pK_a$  of hydroxamic acids are increasing with the increase in dioxan content (mole fraction of dioxan,  $n_2$ ) due to the decrease in the dielectric constant of bulk solvent. As the dielectric constant decreases the ion interaction involving the proton and anionic oxygen on the ligand decreases to a greater extent than the ion dipole interaction between the proton and the solvent molecule. For all hydroxamic acids, the change in  $pK_a$  with mole fraction of dioxan is of considerable magnitude. When the  $pK_a$  of N-p-chlorophenyl-m-substituted benzohydroxamic acids are plotted against the mole fraction of dioxan, linear relationships are observed (Figs. 1-2). The experimental values of  $pK_a$  for almost all hydroxamic acids indicate a maximum deviation from linearity of the order of 0.05 or about 0.5%  $pK_a$ .

Fig. 3. Plots of  $pK_a$ 's of N-p-chlorophenyl-m-substituted benzohydroxamic acids vs  $100/D$  at  $25^\circ\text{C}$ .

### Hammett correlation

Hammett (36) and Jaffe (37) correlated the effect of substitution on the reactivity of benzene derivatives. Agrawal et al. (38-40) have made an attempt to correlate the  $pK_a$  of substituted benzohydroxamic acid with benzoic acid and obtained a good agreement between the two sets of values. In the present investigation a correlation is established between the  $pK_a$  values of N-p-chlorophenyl-m-substituted benzohydroxamic acids with Hammett equation (11).

$$\log \frac{K}{K_0} = \rho \sigma \quad (11)$$

where  $\rho$  is the reaction constant,  $\sigma$  is the substituent constant, K and  $K_0$  are the  $pK_a$  of substituted hydroxamic acids and unsubstituted hydroxamic acids respectively.

The  $pK_a$  in Table 6 indicate that the experimental values (extrapolated), values calculated by Hammett equation and least squares are in good agreement.

A plot of  $pK_a$  of N-p-chlorophenyl-m-substituted benzo-hydroxamic acids against the  $pK_a$  of respective benzoic acids is linear (Figs. 4-7) in aqueous (extrapolated) and 50-70% dioxan-water media and ~~are~~ in agreement with the experimental values (Tables 6-9). The dependence of the acidity on substitution on benzene nucleus was followed by the same

reaction constant,  $\rho$ , obtained by two different plots (Figs. 4-7 and 8).

#### Substituent effect

In order to understand the relation between the molecular structure of hydroxamic acids and their  $pK_a$ , it is convenient to examine the parent carboxylic acids.

The hydroxamic acids under study are derived from m-substituted benzoic acids and follow the order of  $pK_a$  of the benzoic acids, in all mole fractions of dioxan, thus  $pK_a$  of benzoic acids  $CH_3 > H > CH_3O > F > I > Cl > Br > NO_2$

$pK_a$  of hydroxamic acids  $CH_3 > H > CH_3O > F > I > Cl > Br > NO_2$ .
